Question 1.
The code splits the string {{my_str}} into words, then appends every second word starting from the second one (index 1) into the list {{res}} using a while loop

```
res = my_str.split()[1::2]
```

Question 2.

The code loops through the numbers from 100 down to 1 (step -3), and checks if each number is divisible by n. If so, it stores a message saying it is divisible. Otherwise, it stores the remainder of that number divided by n. Finally, it prints all the messages stored in the dictionary.

```
print(*(f"{x} is divided by {n}." if x % n == 0 else f"the remainder of {x} divided by {n} is: {x % n}." for x in range(100, 0, -3)))
```

Question 3.
The code iterates from 0 to the largest ASCII code among '9', 'z', and 'Z' (which is 122). For each number, it checks if the corresponding character is a letter or a digit. If so, it prints the ASCII number and the corresponding character.

```
print(*(f"The ASCII number {i} represents the char '{chr(i)}'" for i in range(0, max(ord('9'), ord('z'), ord('Z')) + 1) if chr(i).isalpha() or chr(i).isdigit()))
```

Question 4.
The code takes a list of ASCII values (list_c), converts each to its corresponding character using chr(), joins them into a single string, and prints it.

```
print(''.join(map(chr, list_c)))
```
